

Triton's Mozambique project yields far more high grade graphite than expected

✘ It was only two weeks ago that Triton Minerals (ASX: TON) announced that, even at its initial stage, reverse circulation drilling at the Company's Nicanda Hill prospect, part of the Balama North graphite project intercepted 220 meters of continuous graphite mineralization in a single bore hole. Drilling has continued since then and Triton continues to reveal its tremendous potential having now reached 316 meters of cumulative width of graphite mineralization in a single diamond hole at the Nicanda Hill prospect. The Nicanda Hill prospect alone may host as much as 480 million tons of graphite mineralization. In total, Triton has intersected – holes and trenches – a strike length of some 1,750 meters at Nicanda Hill.

This is a very impressive start to the program, considering that significant graphite mineralization has been identified in all holes drilled to date. By all means the 220 meters in a single borehole announced on May 19 was a great success; to have 316 meters is a great and encouraging surprise. Triton Minerals is estimated to hold between 730 million and 1.2 billion tons of graphite mineralization at the three prospects that constitute the North Balama project. The rapid upgrades emerging from the drilling, however, suggest those already favorable estimates may have to be revised upward. Managing Director, Brad Boyle, believes that the total may amount to be double the size of the original exploration targets. The resource at Balama is rich in volume and it is of a consistently high grade, medium to coarse flake variety of graphite that should be readily upgraded to the kind of purity levels to address the fast rising number of battery and alternative energy applications, driving demand for flake

graphite.

Triton's promise of being the fourth largest graphite deposit in the world (by tonnage) following the evaluation of resources in its concession Cobra Plains North Balama project may well prove to be true. That initial evaluation was published on 26 February based on an inferred resource of 103 million tons at an average grade of 5.52 % graphitic carbon with 5.7 Mt of graphitic carbon content from the Cobra Plains prospect at Balama North. Considering this was a mere "subsidiary" goal, it stands as an impressive result. The real potential, nevertheless, is emerging from the high-grade Nicanda Hill prospect, which has become the focus of drill testing, which has so far supported the idea that the project contains several large deposits of world class graphite.

Triton's project, Balama North, presents significant 'closeology' advantages; this means it benefits from its proximity – 3.5 km northeast – to well known world-class properties such as Syrah Resources, which has a potential of 1.1 billion tons. Not surprisingly, Triton has found significant mineralization over a 10km long stretch featuring high grade flake graphite. Triton has certainly found a very similar style of mineralization, which is very soft and, therefore, faster and cheaper to process – and it is much more energy efficient. This adds to the Balama Project's appeal. Indeed, Syrah Resources, which owns the prospect adjacent to Balama is running one of the lowest cost graphite projects in the world at some USD\$ 500/ton – consider that flake graphite can cost anywhere from USD\$ 1,800 to USD\$ 3,000 per ton. The proximity to Syrah's deposit has, clearly, already started to produce benefits and help Triton fast track into production.

The benefits of Triton's closeology also extend to infrastructure. In fact, Triton's property enjoys direct access to the main highway. This is actually better than Syrah Resources, where access involves having to deal with two rivers. Triton has unimpeded access in and out of the project,

which means it can save a lot of money by not having to build any additional infrastructure. Triton has completed various phases of exploration programs in 2013 and in all cases, the Company reported that it obtained high grade of graphite. Much of the Balama graphite deposit is largely visible as it rises above ground, reducing the need for costly drilling. Mozambique is rich in resources such as coal and has a long coastline on the Indian Ocean marked by good ports such as Nacala and Beira which facilitate export.

InvestorIntel Video Interview Posted June 3, 2014: Triton may have “double” the original estimation for the graphite exploration targets

Triton’s Balama North graphite project potential is positioned to be leader

✘ April 3, 2014 – Brad Boyle, Managing Director for Triton Minerals Limited (‘Triton’, ASX: TON), speaks to Tracy Weslosky, Editor-in-Chief and Publisher of InvestorIntel, about the Balama North graphite project in Mozambique. Brad starts by noting that since the beginning of 2014, Triton has achieved an “inferred resource on the Cobra Plains prospect and turn that into 103 million tons deposit with an average grade of 5.5%, which is pretty exciting for us because that wasn’t our primary target; that was just the tail end of where we were primarily looking, while we’re waiting for Nicanda Hill to come online.”

Triton’s project, Balama North, as Tracy observes, presents significant ‘closeology’ advantages; this means it benefits

from its proximity – 3.5 km northeast – to well-known world-class properties such as Syrah Resources, which has a potential of 1.1 billion tons. Not surprisingly, Triton has found significant mineralization over a 10km long stretch featuring high grade flake graphite: “one of the main reasons why we picked this project was because of how close it was to that.” Brad adds: “luckily enough it seems that we may have found a very similar style.”

On the financial and management front, Triton made a private placement earlier this year for over four million dollars. Tracy notes that, usually, private placements tend to bring share prices down whereas in the case of Triton, the share price went up. Brad explains this favorable, if unusual, market response, attributing the result to investors who approached Triton and who were keen to see drilling get underway as soon as possible; therefore, they came up with the necessary funds. Triton called a trading halt, which only seemed to spark more interest: “we were oversubscribed by nearly twice what we asked for”. The fact that the share price has not dropped to the pre-placement values suggests investors are very confident about Triton and its ability to deliver. The proximity to Syrah’s deposit has, clearly, already started to produce benefits and help Triton fast track into production.

The benefits of Triton’s closeology also extend to infrastructure. In fact, Triton’s property enjoys direct access to the main highway. This is actually better than Syrah Resources, where access involves having to deal with two rivers. Triton has unimpeded access in and out of the project, which means it can save a lot of money by not having to build any additional infrastructure. The road is there and “it is a straight drive to the port of Pemba”.

As Brad presents the main goals for 2014, having delineated the inferred resource in 2013, the next stage will be to

perform the metallurgical test work, which will occur in the next few weeks, giving an indication of what the recoverable grades will be. A scoping study will follow and it should be completed by the middle of the year. Triton believes it has gathered sufficient data to predict that its resource may be significantly greater than current estimates. The presence of an anomalous graphitic zone extending west and north from its Nicanda Hill prospect, indicating that the "numbers could be very substantial indeed".
